PROJECT BUGGY GAMMA FALLOUT FIELD

Abstract

The gamma radiation early fallout field of the Buggy Event was measured and documented. The radioactive decay of the field with time was also followed. Isoexposure rate contour maps of the fallout field are presented. Analysis of the information collected shows that approximately 3.3% of the gamma-emitting radioactive material produced was deposited beyond the area of continuous ejecta in the fallout field.

Introduction

OBJECTIVES

The objectives of this phase of the Buggy Event were: (1) to provide ground level gamma fallout field measurements for estimating the total gamma radioactivity vented and deposited in early fallout; (2) to provide fallout field contours from this test event for use in normalizing fallout prediction models; and (3) to determine whether the amount of radioactivity deposited in early fallout from a nuclear row charge is significantly different from that resulting from a single cratering detonation.

BACKGROUND

Ground surface gamma fallout exposure rates have been measured following almost every uncontained test shot since Trinity. The resulting fallout contours are summarized in Ref. 1 and subsequent publications by the Army Nuclear Defense Laboratory. Prior to Buggy, only four nuclear cratering events had been conducted by the USA which were useful as fallout experiments for cratering. These were Teapot-ESS, Danny Boy, Sedan, and Cabriolet. We eliminated the Jangle Underground Event because it was buried at too shallow a depth, and the Palanquin Event because of its abnormal venting. Thus, Buggy is a significant addition to our small number of experiments. Also, Buggy is unique in being the first nuclear row charge experiment.

For the Buggy Event, a number of different agencies and laboratories measured gamma radiation. All the known pertinent information available from these sources is included in this report. The authors served as field coordinates, collected the available data from the various participants, reduced the raw data, and formulated the results presented in this report.

~~SECRET~~

Experimental Procedure

SHOT PARTICIPATION

Project Buggy was the first nuclear row cratering detonation executed as part of the Plowshare Program for developing nuclear excavation techniques. Five nuclear explosives, each with a yield of 1.1 kt, were detonated simultaneously at 0904:00.111 PST, 12 March 1968. The explosives were detonated at depths of 135 ft, and were spaced 150 ft apart. The experiment took place on Chukar Mesa, Area 30, Nevada Test Site, in a dry, complex basalt formation. Surface ground zero (SGZ) coordinates of the end emplacement holes designated as U30a and U30e were:

	<u>U30a</u>	<u>U30e</u>
NTS grid coordinates:	N 821,828.24 E 586,630.95	N 822,039.76 E 586,069.54
Latitude:	N 37° 0' 26.9695"	N 37° 0' 29.0784"
Longitude:	W 116° 22' 11.8817"	W 116° 22' 18.7955"

The line of charges was on a bearing of N 69° 21' 05" W. Ground elevations at each hole were:

	<u>Hole U30</u>				
	<u>A</u>	<u>B</u>	<u>C</u>	<u>D</u>	<u>E</u>
Elevation, MSL (ft)	5208.28	5210.04	5210.52	5209.47	5208.42

The principal objectives of the experiment were: (1) to determine nuclear row crater parameters through level terrain in a hard, dry rock; and (2) to determine the fraction of radioactivity which escapes the immediate cratered area.

The dimensions of the resultant crater are:

Apparent crater width, average (W_a)	254 ft
Apparent crater depth, maximum (D_a)	69.8 ft
Lip crest width, average (W_{al})	355 ft
Apparent crater length (L_a)	865 ft
Apparent lip height, average (H_{al}) sides	41 ft
Apparent lip height, average (H_{al}) ends	14 ft
Apparent crater volume	262,456 yd ³
Apparent lip volume	422,205 yd ³

The approximate dimensions of the cloud at +72 sec, the time of maximum initial growth, were:

Base surge diameter	4,500 ft
Base surge height	780 ft
Plume height	2,200 ft
Plume diameter	900 ft

GENERAL DESCRIPTION OF STATIONS

Gamma radiation exposure rate measurements in the Buggy fallout field were made by several organizations using different detection equipment.

The Reynolds Electrical and Engineering Company (REECo) remote area monitoring system (RAMS) consisted of 17 units connected by wire to a central trailer at the Command Post (CP). The individual stations were Neher-White ionization chambers mounted on stakes 3 ft above ground level.

REECo also deployed 22 gamma intensity time recorders (GITR) throughout the fallout field. Each of these stations was self-contained and consisted of a Neher-White ionization chamber mounted on a stake 3 ft above ground level, an Esterline-Angus recorder, and a portable gasoline generator. Each recorder semi-logarithmically plotted exposure rate versus time within a preset range of three decades.

Lawrence Radiation Laboratory, Livermore placed 45 units of its gamma telemetry system² at fixed locations. This system consisted of individual stations connected to a trailer at the CP via VHF radio. Each unit consisted of an ionization chamber mounted on a tripod 4 to 5 ft above ground level and the associated electronics, battery, and radio transmitter-receiver.

REECo mobile radiological safety monitoring teams measured exposure rates with hand-held Victoreen Radector AGB-500-B-SR instruments. U. S. Public Health Service mobile monitoring teams also made measurements, using primarily E-500B instruments; these were outside the Nevada Test Site boundary and at a considerable distance from ground zero (GZ).

STATION LOCATIONS

Figures 1, 2 and 3 show locations of the REECo stations, the gamma telemetry stations of LRL K-Division, the fallout trays of LRL Radiochemistry Div., the mobile monitoring team stakes, and all other pertinent positions where exposure-rate measurements were recorded.

The locations of all remote monitoring stations, with the exception of the LRL gamma telemetry system, are controlled by the requirements of reentry and radiological safety, and were positioned by the Health and Safety Office, LRL-Nevada. The authors were responsible for the location of the LRL gamma telemetry units.

The technique used to position the gamma telemetry units depended on the predicted fallout pattern, fallout sector, throwout or ejecta range and base surge radius; and also on terrain adaptability, the number of units available, location of other remote monitoring systems, and a reasonable minimum exposure rate value to be detected. Reference 3 contains a detailed discussion of the technical and practical techniques used in placing the LRL gamma telemetry units.

Results

DECAY CURVES

The LRL gamma telemetry system followed the course of the radioactive decay of the gamma radiation field for slightly more than 100 hours. The REECO system was expected to augment these decay measurements; however, the RAMS detectors did not function since all the wires to RAMS units passed too close to GZ and were cut by falling rock within a few seconds after shot time.

Only one GITR station of the 22 deployed produced a trace which was at all believable. Even this was not used because the GITR system measurements failed to correlate with other measurements obtained during the Cabriole Event.

The Buggy early time decay curve, Fig. 4, is the nonweighted, arithmetic average of the log-log normalized decay curves produced by LRL telemetry units 4, 12, 23, 30 and 31. These five stations were selected because they operated uninterrupted for more than 100 hours and their readings did not fall below the lowest level for which the units were calibrated. Each of the five decay curves can be contained within the shaded envelope graphically represented by Fig. 5.

The long-term decay was recorded by repeated hand-held instrument readings taken at stakes around the crater lip. The average slope for the log-log straight line plot of the ten lip stations was -0.9. Figure 6 is a time decay plot of one lip stake location with this average slope.

Appendix A contains the time decay curves from all LRL telemetry stations and the time decay plots for the ten crater lip stake locations.

Fig. 4. Average normalized LRL gamma decay curve.

MONITOR TEAM DATA AND DATA REDUCTION

Monitoring teams conducted radiological surveys following the event. The technique employed was the standard

procedure of marking the various roads and trails with rad-safe survey monitor stakes. Other locations were identified by the location of sampling trays, RAMS units, GTR units, LRL telemetry units, or distinguishable man-made features.

We have converted each monitor team exposure rate measurement to a common time of H+1 hour postshot by use of the early time decay curve, Fig. 4. From these numbers, a best estimate of H+1 hour exposure rate for

FALLOUT EXPOSURE RATE CONTOURS

The fallout pattern contours shown in Figs. 7 and 8 represent isoexposure rate levels at a reference time of H+1 hour. This representation follows a convention well established in the literature; it does not mean that fallout was complete at all locations one hour after detonation. These figures were drawn using the reduced monitor team data presented in Appendix B, and where appropriate, LRL telemetry data. We used plots of log exposure rate versus log distance to interpolate between measured data point locations to establish contour locations. Figure 9 is a plot of exposure rate versus distance downwind along the pattern "hot line."

Fig. 9. Exposure rate versus distance.

Fig. 10. Total exposure versus distance.

TOTAL EXPOSURE VERSUS DISTANCE

The U. S. Public Health Service placed thermoluminescent dosimeters along arcs at various distances downwind. Figure 10 is a plot of total exposure versus distance along the "hot line" taken from their measurements. The dosimeters were recovered from a few days up to seven days after the event. Thus the exposure represents cloud passage radiation and radiation from fallout deposited on the ground.

Discussion

OBSERVED DECAY OF GAMMA FIELD COMPARED TO THEORETICAL DECAY

The total production of fission products and other gamma-emitting radionuclides which made a significant contribution to the gamma radiation field are listed in Table 1.

-11-

Na ²⁴	1.1×10^{22}	34
Mn ⁵⁶	4.4×10^{22}	324
W ¹⁸⁷	1.7×10^{23}	58
Pb ^{204m}	1.0×10^{21}	14
Total fission products		800
	Total:	1230

^aRef. 4.

^bOne fission ton equivalent is that amount of radioactive material which produces the same gamma exposure rate in air as the fission products from one ton of fission.

of fission products alone. And in Fig. 13, the observed average decay is contrasted to the expected decay of the mixture of fission products plus neutron-induced radioactive nuclides. The observed decay is seen to follow the decay of the total mixture the most closely. At H+100 hours, the observed decay is not as great as anticipated. This is probably due to the preferential increase in the relative amount of W¹⁸⁷ present in the mixture and measured by radiochemical analysis. That is, fractionation caused an enrichment in the amount of W¹⁸⁷ in the fallout field.

CALCULATION OF GAMMA ACTIVITY IN EARLY FALLOUT

The areas contained within the isoexposure rate contours previously presented in Figs. 7 and 8 were measured with a planimeter to yield values of gamma radiation exposure rate versus area in square statute miles. This information is plotted in Fig. 14; the integration of these data yields the "exposure rate integral." For Buggy, the value of this integral was 99 R/hr \times mi² for the area from 0.054 mi² (continuous ejecta area) to infinity (see Table 2):

$$\int_{0.054 \text{ mi}^2}^{\infty \text{ mi}^2} R(A) dA = 99(R/\text{hr})_{H+1} \times \text{mi}^2.$$

An expected (quasi-theoretical) time decay curve for the fallout field can be constructed from the information in Table 1; such a curve is given in Fig. 11. When doing this, one assumes a relatively small amount of fractionation in the early fallout pattern. For this Buggy mixture of radionuclides, one would expect the observed gamma field decay to be different from fission products until around H+200 hours. The slope of the observed curve should depart from the fission product line and approximate the line labeled "total" in Fig. 11.

That this was in fact observed to a reasonable degree can be seen from Figs. 12 and 13. In Fig. 12, the observed average decay is contrasted to the decay

Conclusions

FRACTION OF TOTAL GAMMA ACTIVITY DEPOSITED

In the Buggy Event, within the early fallout field an amount of gamma radiation activity equivalent to approximately 40 tons of fission products was deposited. This amount is based on the value of 1 kt of fission products, evenly distributed over 1 mi² (statute) of Nevada Test Site terrain, producing an H+1 hour gamma radiation field of 2500 R/hr. Since the total gamma radioactivity produced by Buggy was equivalent to 1230 tons of fission products at H+1 hour, the fraction deposited in fallout was some 3.3%. The standard deviation of this value is estimated as roughly $\pm 60\%$ of the value. Thus, the deposited fraction has a probability of 0.68 of being between 1.1% and 5.3%, with the most likely value being 3.3%.

This deposited fraction for the Buggy row charge detonation is very similar to the fraction for single charge detonations under comparable conditions. Both Danny Boy and Cabriolet were fired in hard, dry rock at roughly the Buggy scaled depth of burst. In their early fallout patterns, 4% and 2.5% fractions were deposited respectively.

Monitor Team Readings and Reduced Monitor Team Data

Tables B-1, B-2 and B-3 consist of monitor team readings and reduced data taken at three locations. In each table the exposure rates as determined by the monitor teams and the location and time of the readings are given. Also listed are the exposure rates time-corrected to H+1 hour, using the average decay curve for Buggy. Where several readings were made at the same location, the best estimate is given.

Table B-1. Monitor readings at rad-safe road stakes.

Appendix C

Shot-Time Meteorological Conditions

Table C-1 contains a brief summary of the observed shot-time meteorological data.

Table C-1. Meteorological data taken at Buggy I CP.^a

Surface observation at		Buggy I CP, 0903 PST, March 12, 1968			
Weather		2/10 altocumulus-8/10 cirrostratus			
Sky condition		Scattered, overcast			
Visibility		Unrestricted			
Atmospheric pressure		845.9 millibars 5095 ft MSL			
Temperature		10.6°C			
Dew point temperature		-6.3°C			
Relative humidity		30%			
Surface data (from RAOB)		5210 ft MSL, 0903 PST, March 12, 1968			
Atmospheric pressure		840 millibars			
Temperature		6.9°C			
Dew point temperature		-15.2°C			
Relative humidity		19%			
Upper air data at		Buggy I CP, 0903 PST, March 12, 1968			
Height (ft MSL)	Wind (deg/kts)	Pressure (mb)	Temperature (°C)	Dew point (°C)	Relative humidity (%)
5,100 ^b	180/06	846	10.6	-6.3	30
5,210	180/06	840	6.9	-15.2	19
6,000	170/13	818	4.8	-16.9	19
7,000	180/17	788	2.1	-18.6	20

Appendix D Selected Decay Curves

This appendix contains the individual best fit, normalized gamma decay curves (Figs. D-1 through D-5) used to produce the early-time decay curve shown in Fig. 4.

Fig. D-1. LRL gamma telemetry station 4.

Fig. D-2. LRL gamma telemetry station 12.
